ABSTRACT

Background Disasters are events that disrupt the daily functioning of a community or society, and may increase long-term risk of adverse cardiometabolic outcomes, including cardiovascular disease, obesity and diabetes. The objective of this study was to conduct a systematic review to determine the impact of disasters, including pandemics, on cardiometabolic outcomes across the life-course.

Design A systematic search was conducted in May 2020 using two electronic databases, EMBASE and Medline. All studies were screened in duplicate at title and abstract, and full-text level. Studies were eligible for inclusion if they assessed the association between a population-level or community disaster and cardiometabolic outcomes ≥ 1 month following the disaster. There were no restrictions on age, year of publication, country or population. Data were extracted on study characteristics, exposure (eg, type of disaster, region, year), cardiometabolic outcomes and measures of effect. Study quality was evaluated using the Joanna Briggs Institute critical appraisal tools.

Results A total of 58 studies were included, with 24

Strengths and limitations of this study

- This systematic review is one of the first to review the literature on disasters, including pandemics, and subsequent cardiometabolic outcomes throughout the life-course.
- A comprehensive search strategy was used to identify studies that covered a range of disasters (eg, famine, war, terrorism, natural disasters and infectious disease epidemics), periods of exposure from pregnancy, childhood to older adulthood and a wide breadth of cardiometabolic outcomes.
- Only studies published in English were included and a search of the grey literature was not conducted.
- Due to the heterogeneity of studies, a meta-analysis could not be conducted, and results were only synthesised narratively.
- Limited evidence was available on the impact of pandemics specifically, and few studies evaluated proposed mechanisms or risk modification across subgroups of the populations.

LONG-TERM HEALTH OUTCOMES

The impact of disasters, including pandemics, on cardiometabolic outcomes across the life course: a systematic review

Objective

To conduct a systematic review to determine the impact of disasters, including pandemics, on cardiometabolic outcomes across the life course

Methods

- Systematic search conducted in May 2020 on databases EMBASE and Medline
- Assessed association between population-level disaster and any cardiometabolic outcomes ≥ 1 month following the disaster
- No restrictions on age, year of publication, country or population

Study characteristics (n=58)

62% of studies
published in
North America

76% of studies
published from
2010-2020

71% of studies
cohort/longitudinal
design

41% of studies
investigated
pregnancy/childhood
exposure

59% of studies
investigated
adulthood exposure

60% of studies
explored impact of
natural disaster

71% of studies
explored impact on
cardiovascular disease

21% of studies
explored impact on
obesity or BMI

Exposure to disaster and subsequent cardiometabolic outcomes

Number of studies that found increased risk (n=47)	
Exposure to disaster during pregnancy and childhood	
Human-made disasters (n=12)	10
Natural disasters (n=12)	11
Exposure to disaster during adulthood	
Human-made disasters	9
Natural disasters	17

Exposure to disaster and subsequent cardiometabolic outcomes

Number of studies that found increased risk (n=47)	
Exposure to disaster during pregnancy and childhood	
Human-made disasters (n=12)	10
Natural disasters (n=12)	11
Exposure to disaster during adulthood	
Human-made disasters	9
Natural disasters	17

For instance, those in utero during the 1918 Influenza pandemic (born April to June 1919) had 36.7% excess risk of diabetes compared to those born after the pandemic (95% CI: 18.9, 54.4)

Exposure to disaster and subsequent cardiometabolic outcomes

Number of studies that found increased risk (n=47)	
Exposure to disaster during pregnancy and childhood	
Human-made disasters (n=12)	10
Natural disasters (n=12)	11
Exposure to disaster during adulthood	
Human-made disasters	9
Natural disasters	17

For instance, people with higher perceived stress following Hurricane Ike had an average BMI of 28.43 kg/m² compared to those with lower perceived stress who had an average BMI of 20.83 kg/m² (p=0.02)

Key Findings

The burden of disasters extends beyond the known direct harm, attention is needed on the detrimental indirect long-term effects on cardiometabolic health, including obesity.

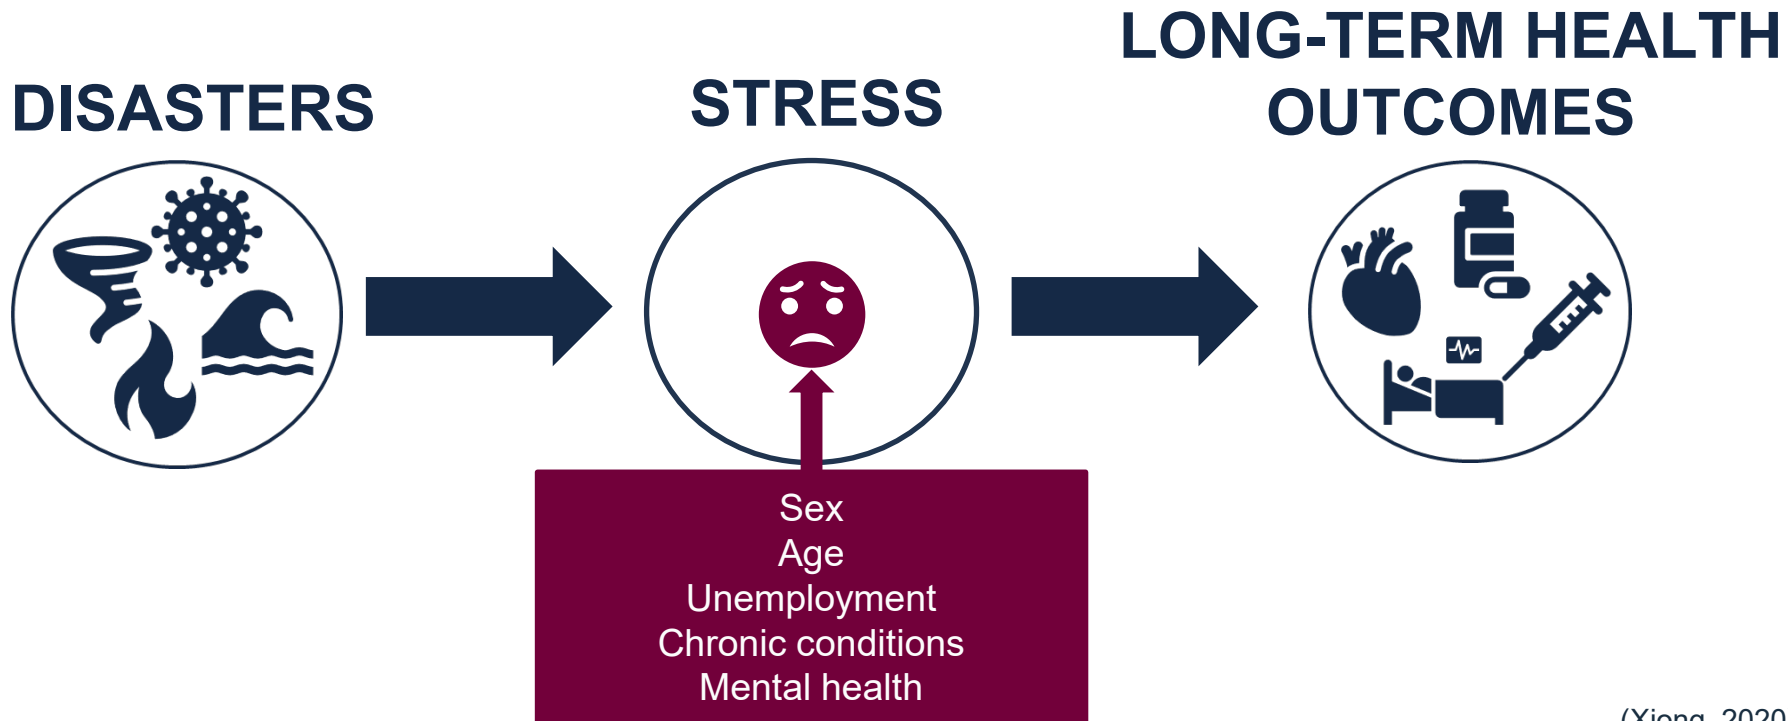

Findings may inform public health prevention strategies to mitigate the impact of disasters, including the COVID-19 pandemic, on future cardiometabolic risk.

Mechanisms underlying this association were not well studied, however, one hypothesized pathway includes stress.

Measures of stress at CLSA COVID-19 Exit Survey

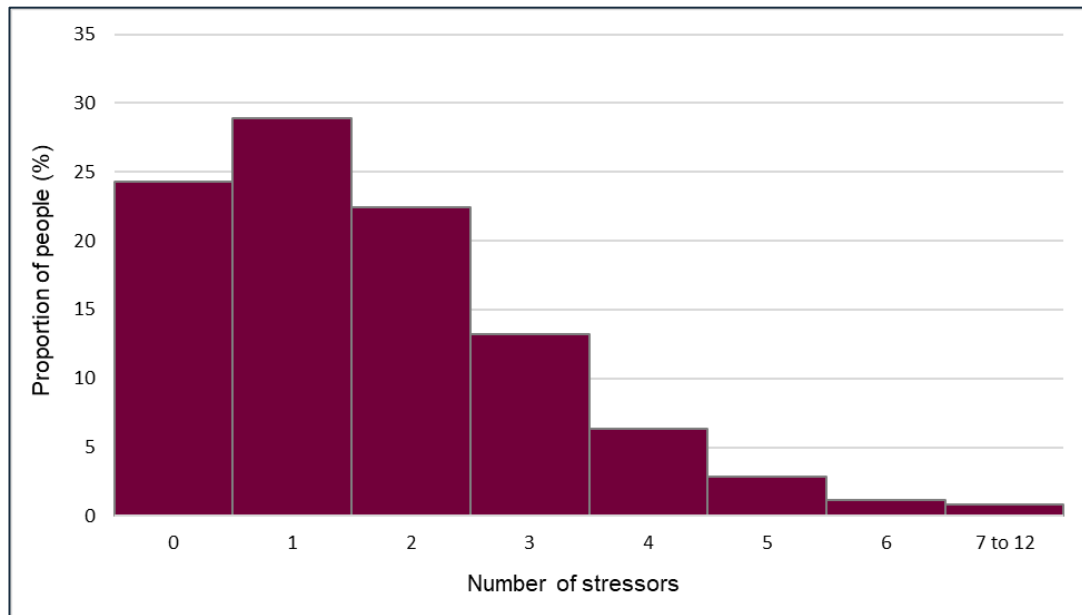

Stressors

Participants were asked if they had experienced any of the 12 stressors since the start of the pandemic:

- Participant ill
- Someone close to participant ill
- Someone close died
- Loss of income
- Unable to access food/supplies
- Increased caregiving
- Unable to care for others
- Unable to access healthcare
- Unable to access prescriptions
- Increased conflict
- Separation from family
- Breakdown in family relationships

1. Adjusted for all variables listed in the table: sex, age group, racial background, education, household income, region, marital status, essential worker status and urban/rural status

Key Findings

Adults across Canada experienced stressors and perceived the consequences of the pandemic as negative, which varied by socioeconomic factors and geography, highlighting inequalities in experiencing stress.

Future research will be needed to determine the impact of stress during the pandemic on future health outcomes and how this varies by socioeconomic factors.

Obesity and adverse childhood experiences in relation to stress during the COVID-19 pandemic: an analysis of the Canadian Longitudinal Study on Aging

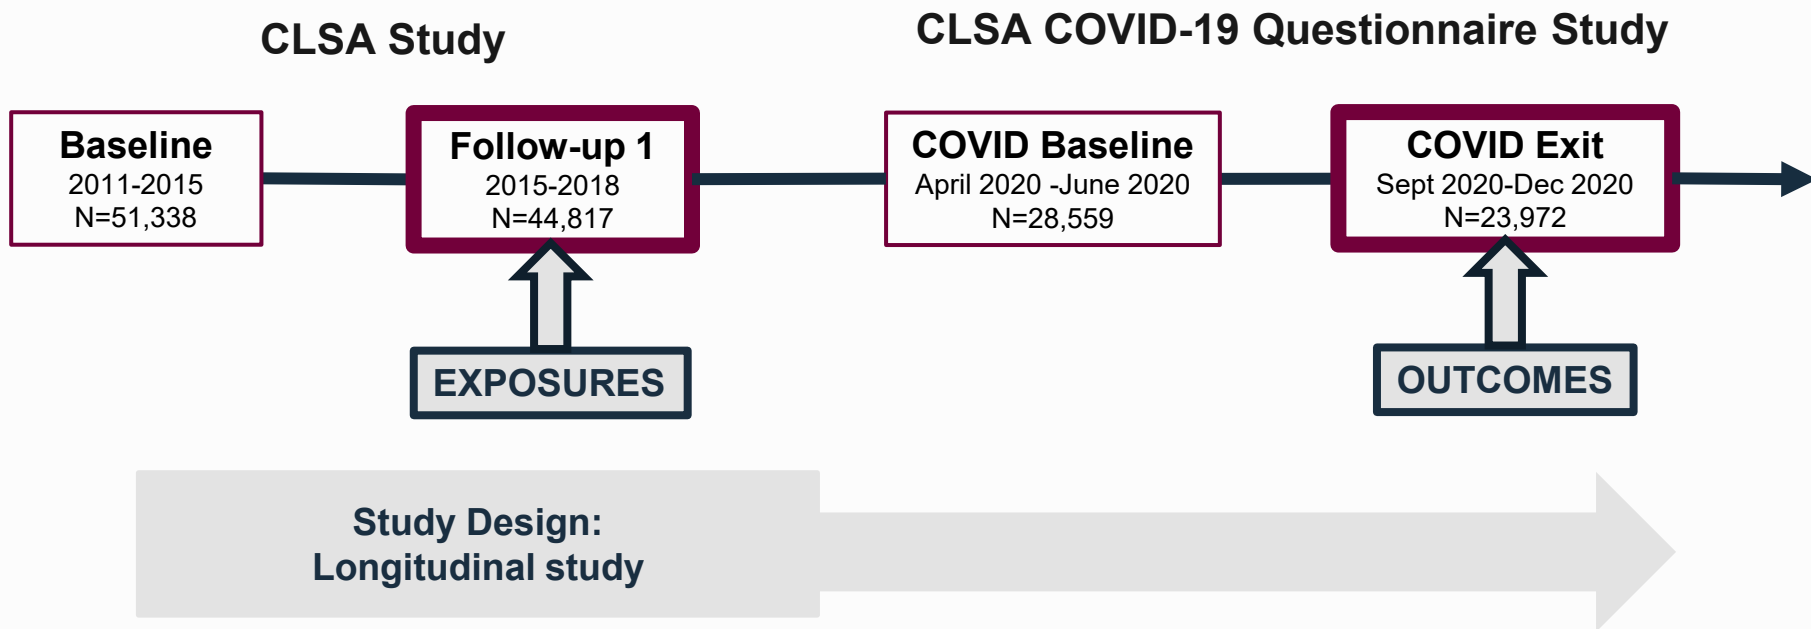

Vanessa De Rubeis, Andrea Gonzalez, Margaret de Groh, Ying Jiang, Urun Erbas Oz, Jean-Eric Tarride, Nicole E. Basta, Susan Kirkland, Christina Wolfson, Lauren E. Griffith, Parminder Raina, Laura N. Anderson on behalf of the Canadian Longitudinal Study on Aging (CLSA) Team

Published in International Journal of Obesity

Objectives

- 1** To evaluate the associations between
 - (1) ACEs and stress during the pandemic
 - (2) obesity and stress during the pandemic
- 2** To examine if the association between obesity and stress during pandemic is modified by ACEs

Data source & Study design

Exposure 1: Adverse Childhood Experiences (ACEs)

Participants asked to report which of the following 8 ACEs they experienced before the age of 18:

Parent divorce

Physical abuse

Sexual abuse

Emotional abuse

Parent death

Intimate partner violence

Neglect

Family mental health problems

Exposure 2: Obesity

Height and Weight
Measured or self-reported

BMI

Normal: $\leq 24.9 \text{ kg/m}^2$

Overweight: $25.0\text{-}29.9 \text{ kg/m}^2$

Obesity class I: $30.0\text{-}34.9 \text{ kg/m}^2$

Obesity class II: $35.0\text{-}39.9 \text{ kg/m}^2$

Obesity class III: $\geq 40.0 \text{ kg/m}^2$

Statistical analyses

Objective 1

PROC GENMOD to estimate relative risks (RRs) and 95% confidence intervals
Models adjusted for sex, age group, racial background, physical activity, household income, alcohol consumption and depression

Objective 2

The adjusted association between ACEs, obesity and stress among Canadian adults at CLSA COVID-19 Questionnaire Exit Survey (September-December 2020)

As obesity level increases, risk of reporting additional stressor increases

1. Adjusted for sex, age

anxiety and depression

Objective 2: The association between obesity and stress during the pandemic modified by ACEs

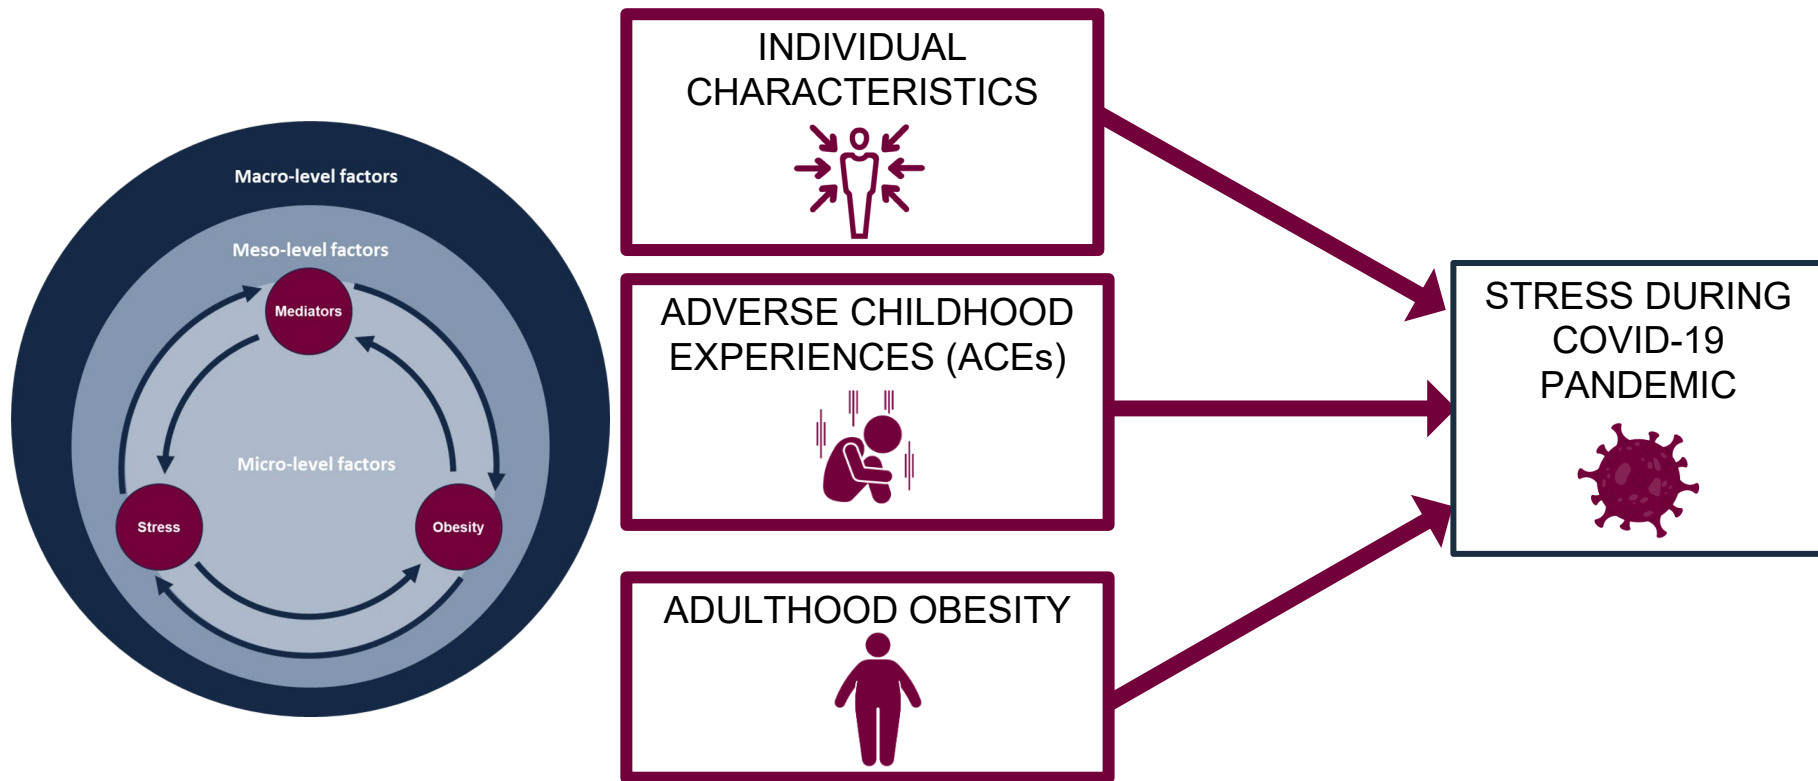

Key Findings

Experiences across the life course, including obesity and ACEs were associated with increased stress during the COVID-19 pandemic, confirming subgroups of people are more susceptible to stress associated with a stressful event.

Important for future research to determine the long-term effects of stress during the pandemic.

Conclusions

Strengths

First studies to describe the stress and associated factors during pandemic in Canada

CLSA is a large nationally generalizable sample with a population-based sampling strategy

Surveys collected by phone and web to accommodate limited internet access

Future waves of data being collected by CLSA allow for longitudinal research on how stress during pandemic impact health outcomes

Limitations

Participants were primarily white limiting the representativeness

Stressor list was developed early in the pandemic and did not include all possible stressors

Perceived stress scale not included

COVID-19 questionnaire data collected in the first two waves of the pandemic in Canada

Future research

1

Additional mechanistic pathways need to be explored to help develop prevention strategies

2

Continued research needed on the lasting effects of the COVID-19 pandemic

Stressors and perceived consequences of the COVID-19 pandemic among older adults: a cross-sectional study using data from the Canadian Longitudinal Study on Aging

Vanessa De Rubels MPH, Laura N. Anderson PhD, Jayati Khattar BSc, Margaret de Groh PhD, Ying Jiang MD MSc, Unn Erika Øst, Nicole E. Basta PhD, Susan Kirkland PhD, Christina Wolfson PhD, Lauren E. Griffith PhD, Paminder Raina PhD, the Canadian Longitudinal Study on Aging Team

Abstract

Background: The indirect consequences of the COVID-19 pandemic in older adults, such as stress, are unknown. We sought to describe the stressors and perceived consequences of the COVID-19 pandemic in older adults in Canada and to evaluate differences by socioeconomic factors.

Methods: We conducted a cross-sectional study using data from the Canadian Longitudinal Study on Aging COVID-19 Exit Questionnaire (September–December 2020). A 15-item checklist was used to assess stressors (e.g., income loss, separation from family) experienced during the pandemic, and a single question was used to measure perceived consequences. We used a generalized linear model with a binomial distribution and link to estimate prevalence ratios (PRs) and 95% confidence intervals (CIs) for the association between socioeconomic factors, stressors and perceived consequences.

Results: Among the 23972 older adults (aged 50–66 yr) included in this study, 17777 (75.9%) reported at least 1 stressor during the pandemic, with 5796 (24.4%) experiencing 3 or more stressors. Of the 23205 participants who reported on their perceptions of the consequences of the pandemic, 14520 (62.1%) participants perceived the consequences to be negative. Females were more likely to report most stressors than males, such as separation from family (adjusted prevalence ratio 1.31, 95% CI 1.28–1.35). The perceived consequences of the pandemic varied by region: residents of Quebec were less likely to perceive the consequences of the pandemic as negative (adjusted prevalence ratio 0.87, 95% CI 0.84–0.91) than those of the Atlantic provinces.

Interpretation: These findings suggest that older adults across Canada experienced stressors and perceived the pandemic consequences as negative, though stressors and perceptions of consequences varied by socioeconomic factors and geography, highlighting inequalities. Future research will be needed to estimate the impact of stress during the pandemic on future health outcomes.

physical activity facilities, closures) may contribute to increased incidence of obesity, cardiovascular disease and type 2 diabetes, however, it has been hypothesized that chronic stress, in particular, may influence disease development.¹²

BACKGROUND: People with obesity are at increased risk of chronic stress, and this may have been exacerbated during the COVID-19 pandemic. Adverse childhood experiences (ACEs) are also associated with both obesity and stress, and may modify risk of stress among people with obesity. The objectives of this study were to evaluate the associations between obesity, ACEs, and stress during the pandemic and to determine if the association between obesity and stress was modified by ACEs.

METHODS: A longitudinal study was conducted among adults aged 50–66 years ($n = 23,972$) from the Canadian Longitudinal Study on Aging (CLSA) COVID-19 Study. Obesity and ACEs were collected pre-pandemic (2015–2018), and stress was measured at COVID-19 Exit Survey (Sept–Dec 2020). We used logistic, Poisson, and negative binomial regression to estimate relative risks (RRs) and 95% confidence intervals (CIs) for the associations between obesity, ACEs, and stress outcomes during the pandemic. Interaction by ACEs was evaluated on the additive and multiplicative scales.

RESULTS: People with obesity were more likely to experience an increase in overall stressors (class II obesity vs. healthy weight $RR = 1.19$; 95% CI: 1.12–1.27) as well as increased health related stressors (class II obesity vs. healthy weight $RR = 1.25$; 95% CI: 1.12–1.39) but did not perceive the consequences of the pandemic as negative. ACEs were also associated with an increase in overall stressors (4–8 ACEs vs. none $RR = 1.38$; 95% CI: 1.33–1.44) and being more likely to perceive the pandemic as negative (4–8 ACEs vs. none $RR = 1.32$; 95% CI: 1.19–1.47). The association between obesity and stress was not modified by ACEs.

CONCLUSIONS: Increased stress during the first year of the COVID-19 pandemic was observed among people with obesity or ACEs. The long-term outcomes of stress during the pandemic need to be determined.

INTRODUCTION

Stress and obesity share a complex relationship, with cyclical and bidirectional associations across the life course^{1,2}. As described in a conceptual model by van der Valk et al., the bidirectional interplay between obesity, chronic stress, and glucocorticoid action is impacted by numerous individual level characteristics, including genetics, lifestyle, medications and mental distress¹. "It is well known that stress and obesity are associated", and many mechanistic pathways that lead to disease development exist, including health behaviors, glucocorticoid activation, and metabolic health^{1,3,4}. However, having obesity has also been found to

increase stress due to several reasons, including comorbidities that limit daily activities, and weight stigma or bias, which may induce a prolonged stress response⁵. Adverse childhood experiences (ACEs), defined as a wide range of negative events, including abuse, neglect, witnessing violence, parental mental illness or incarceration of a family member⁶, are one example of an individual level factor that may impact both obesity and stress^{7–9}. Although ACEs take place early in life, the effects have been found to extend beyond childhood or adolescence into older adulthood¹⁰. Following exposure to ACEs, there may be a prolonged stress response, which is also known as toxic stress,

Abstract Disasters are events that disrupt the daily functioning of a community or society, and may increase long-term risk of adverse cardiometabolic outcomes, including cardiovascular disease, obesity and diabetes. The objective of this study was to conduct a systematic review to determine the impact of disasters, including pandemics, on cardiometabolic outcomes across the life-course.

Design: A systematic review was conducted in May 2020 using two electronic databases, EMBASE and Medline. All studies were screened in duplicate at title and abstract, and full-text level. Studies were eligible for inclusion if they assessed the association between a population-level or community disaster and cardiometabolic outcomes.

Results: A total of 58 studies were included, with 24 studies reporting the effects of exposure to disaster during pregnancy/childhood and 34 studies reporting the effects of exposure during adulthood. Studies included exposure to natural ($n=35$, 60%) and human-made ($n=23$, 40%) disasters, with only three (5%) of these studies evaluating previous pandemics. Most studies reported increased cardiometabolic risk, including increased cardiovascular disease incidence or mortality, diabetes and obesity, and increased risk of cardiovascular disease. Most studies evaluated the biological mechanisms or high-risk subgroups that may be at a greater risk of adverse health outcomes following disasters.

Conclusions: The findings from this study suggest that the impact of disasters extend beyond the known direct harm, and attention is needed on the detrimental indirect long-term effects on cardiometabolic health. Given the current COVID-19 pandemic, these findings may be useful to help health prevention strategies to mitigate the impact of future cardiometabolic risk.

Strengths and limitations of this study

- This systematic review is one of the first to review the literature on disasters, including pandemics, and subsequent cardiometabolic outcomes throughout the life-course.
- A comprehensive search strategy was used to identify studies that covered a range of disasters (eg, famine, war, terrorism, natural disasters and infectious disease epidemics), periods of exposure from pregnancy, childhood to older adulthood and was wide and not publication-biased.
- Only studies published in English were included and a search of the grey literature was not conducted.
- Due to the heterogeneity of studies, a meta-analysis could not be conducted, and results were only synthesized narratively.
- Limited evidence was available on the impact of pandemic disasters, and few studies evaluated proposed mechanisms or risk modification across subgroups of the target populations.

BACKGROUND

Disasters, as defined by the WHO, are events that disrupt the daily functioning of a community or society, causing material, economic or environmental losses, overwhelming local capacities.¹ Disasters can be categorized into natural disasters, human-made disasters and hybrid disasters.² Natural disasters include regular phenomena above and beneath the earth's surface (eg, tsunamis or landslides), meteorological phenomena (eg, tornadoes or floods) or other natural phenomena (eg, epidemics and pandemics).³ Human-made disasters include adverse transportation incidents, technological events (eg, fire or toxic leaks), terrorism, warfare or conflict.⁴
